three irregular subterminal bletches between veins Cu2 and M2; a series of black dots along costo, increasing in size near apex; a small black patch at origin of veins Cui and M3 and a similar one on second anal vein obliquely below it; inner margin with several fine black strigae; on outer margin a series of black dashes, of which the apical ones are perpendicular to the margin, that between veins M1 and R5 being the longest and most prominent; the lower ones are oblique and bordered inwardly with white. Secondaries dark gray, lighter at base, with traces of marginal row of white spots; fringes on both wings checkered white and gray.

Beneath much as above; white subterminal patches less prominent; terminal black dashes very clear; secondaries, lighter than above, white, sprinkled heavily with gray; veins bordered terminally with a series of black dots.

Expanse, 29 mm.

Habitat.—Eureka, Utah (T. Spalding). I &. Type Coll.

Somewhat similar to our species falmata, but differing in Barnes. venation. As it was late to include a figure in our revision of North American Cossidae, just published, we reproduce it on the accompanying plate, together with ethela N. & D., of which species the above mentioned work only figures a very poor specimen, the only available one at the time.

Mallophaga from Islands off Lower California. By V. L. Kelloge and W. M. Mann, Stanford University, California.

The following determinations and descriptions of new species of bird-infesting Mallophaga are made from a collection taken by R. C. McGregor in 1897 from birds of the islands off the coast of Baja California. The determinations of the birdhosts were made by McGregor, an accomplished ornithologist. The parasites were taken from the fresh bird specimens.

The collection is of special interest on account of the relation of the host species to the birds of the Galapagos Islands, from which two collections of Mallophagan parasites have been studied at Stanford (see, "Mallophaga from Birds of the Galapagos Islands," by Kellogg and Kuwana, in Proc. Wash. Acad. Sin Vol. 17. p. 457-460. Sept., 1902; and "A Second Collection of Malleghaga from Birds of the Galapagos and Revillagigedo Islands and Neighboring Waters," by Kellogg, in Trans. Amer. Ent. Soc., Vol. XXXII, pp. 315-324, Nov., 1906). The birds of the Galapagos Islands are believed to be descendants, either unmodified, or modified to be new species and new genera, of species of the western coast of northern South America, Central America and Mexico.

In the light of this presumption and in the light of the fact that those Mallophagan species found so far on more than one host species are usually found on related host species, the comparison of a Mallophagan collection from birds of the West Coast of America (south of the United States) with the full collections already made from the Galapagos birds might be expected to turn up a number of interesting cases of host distribution. And this expectation finds some realization in the present opportunity.

Of the Mallophagan species included in this collection from birds of the islands off Baja California, fifteen have been also recorded from birds of the Galapagos Islands. Among these cases of common occurrence the taking of Docophorus spectyti Osborn, recorded from Spectyto rostratus and Spectyto hypogaea from Baja California, from Spectyto sp. of the Galapagos Islands is of special interest, as is the taking from Anous stolidus of the Galapagos Islands of Colpocephalum milleri recorded from Anous ridgwayi from Baja California.

Docophorus acanthus Giebel.

A single specimen from *Haematopus bachmanni*, San Benito Island.

Docophorus Iari Denny.

Two males from Aechmophorus occidentalis, Ensenada Isl.

Docophorus platystomus Nitzsch.

Two specimens from Haliaeetus leucocephalus, Todos Santos Island.

Docophorus californiensis Kellogg var. quadripustulatus var. nov. In the collection are four specimens that differ markedly from typical californiensis in having most of the hairs on the

of the men distinctly pustulate and regularly arranged, four in a rear. Equidistant on each side of the row, close to the posterior narrain of the segment is an additional pustulate hair. On the sixth segment there are only two central hairs, and on the perultimate and last segments only the marginal hairs are pustulate. This variety is somewhat larger than the typical form timales 1.90 mm.). One male and one female from *Pipilio carmani*, Socorro Island; two specimens from *Conurus holochlerus*, Socorro Island.

Docophorus breviantennatus Piaget.

Three males and two females referable to this species, from *Phaethon aethereus*, Socorro Island. Another male from *Sula gossi*, San Benidicte Island. *Docophorus breviantennatus* approaches most closely *D. validus*, but the connected dorsal bands of the former will at once distinguish it.

Docophorus speotyti Osborn.

Five specimens from Spectyto rostratus, Clarion Island, and others from Spectyto hypogeae, San Benito Island.

Docophorus insolitus Kellogg.

Two males from Ptychoramphus aleuticus, San Geronimo Island.

Docophorus montereyi Kellogg.

A single specimen from Brachyramphus hypoleucus, San Benito Island.

Docophorus sp. juv.

Two specimens, too young to identify positively, probably undescribed, from *Haematopus frazeri*, San Martin Island.

Nirmus faralloni Kellogg.

One specimen from Arenaria melanocephala, San Geronimo Island.

Two specimens from Larus heermani, San Geronimo Island.

Nirmus latifasciatus Piaget.

One specimen from Haematopus frazeri, San Martin Island.

Nirmus gloriosus Kellogg and Kuwana.

One male and two females from Sterna anaetheta, Socorro Island.

Nirmus cuprepes Kellogg and Clapman.

Male and female from Arenaria melococoplets, San Martin Islanda

Nirmus caracarensis n. sp.

Three males from a caracara, Polyborus lentoses, Guade-loupe Island. This specimen most closely approaches N. splendidus Kellogg, but differs in the much smaller size, the broadly rounded clypeus, and the markings. It is perhaps related both to splendidus and to N. discocephalus Nitzsch, and the three species form a group distinguished by the broad abdomen and rounded head. The three species infect raptorial birds. Splendidus was found on Polyborus cheriway.

Description of the male.—Body, length 1.76 mm.; width .73 mm.; form broad, color whitish with brown markings, thorax entirely brown, head broad and rounded and, except clypeus and signature, brown.

Head, length .57 mm.; width, .48 mm.; forehead broad between trabeculae, sides converging, straight to near front, which is broad and rounded; forehead with five short separated hairs on each side, trabeculae large for Nirmus; antennae short, uncolored; eye large, prominent with a long hair, and a fine prickle just behind it; temporal margins evenly rounded, with two long hairs; occipital margin concave; whole head except the signature and clypeus, brownish; antennal bands narrow, a little darker than the general color of head, running entirely around frontal margin of head, paler in front; trabeculae uncolored.

Prothorax short, with one hair in posterior angles; segment wholly colored; metathorax short, the whole thorax about one-half as long as head, and obtusely angulated on abdomen; two very long hairs on lateral margin, and posterior margin with two long hairs on each side; segment entirely grown; legs pale.

Abdomen ovate; posterior angles of segments 1 and 2 without hairs, segments 3 and 4 with a single hair, succeeding segments with two hairs; dorsal surface of each segment with about fifteen long hairs arranged in a single transverse row; posterior segments with fewer hairs, whitish with an uninterrupted transverse brown blotch on each segment; segment 9 rounded behind, with numerous longish hairs; uncolored except where the chitinized genitalia show through, the genital blotch not distinct.

Nirmus melanococcus Carriker.

Two females from Mimodes greysoni, Socorro Island. Melanococcus was described from a single female collected on

Phonga bidentata sanguinolenta in Costa Rica. Our specimens have a head much larger than that figured by Carriber, and may possibly be a distinct variety, but the breekpik and group (to which this species belongs) is at present too little known to justify the gloing of names in it on slight differences.

Nirmus lucidus n. sp.

One adult female and two immature specimens from the marbled godwit, Limosa fedou, Playa Maria Bay. This species is close to Osbern's N. cordatus, but the more general clongate form of lucidus will at once separate it from that species.

Description of females-Length 2.2 mm.; width .6 mm.; elongate; color clear, with translacent brownish yellow markings; rather Lipeuroid in general appearance.

Head, length 125 mm.; width 143 mm.; pale brownish yellow; sides slightly convex, and broadly rounded front; clypeus flatly rounded in front; trabeculae very small, colorless; antennae short and thick, colored same as head; eye flat, colorless, with one fine bristle; light-colored antennary bands converging in front, the space between them clearer but with darker triangular mark; mandibles light brown in color.

Prothorax small, sub-quadrangular, sides convex; narrow light brownish-yellow lateral bands almost unite at middle of posterior margin; coxal markings showing through as brownish yellow blotches. Metathorax larger, form similar to that of prothorax, except for obtusely angulate posterior margin; marginal bands distinct, though faintly colored; hairs on side very weak; coxae showing through as brownish yellow blotches; legs stout, tibiae brownish yellow, femora with large yellow spot, otherwise colorless.

Abdomen elongate elliptical, widest at fourth segment; posterior angles of segments little rounded, with a single marginal hair except on the first two segments; dorsum with short scattered hairs; color clear without marginal bands; transverse blotches light yellowish brown in color, extending width of segments, not interrupted; last segment with very faint blotch.

Nirmus nesiotes sp. nov.

One female from Haematopus bachmani, San Martin Island. This new Nirmus approaches Piaget's coniceps and Carriker's rhamphasti, the first from a hornbill, the other from a toucan. It is rather remarkable to find such closely related Mallophagous species on birds as widely separated as to relationship.

The new species is closest to rhamphasti but can be distinguished from it by the note of agate form, the testaceous protionade leads, only slightly interrupted at middle, the more clougate head, and the head markings.

Description of female.-- Body, length 2 mm., width .66 mm., moderately robust, for the most part clear with distinct testaceous markings and a piecous brown abdominal margin.

Head, length .75 mm.; width .48 mm.; front conical, broad, slightly concave at apex; sides slightly concave with four short hairs; clypeus clear, slightly emarginate in front; trabeculae short, colorless; antennae colorless, short, of medium thickness, the second segment longest; temples little rounded, expanded slightly anteriorly and posteriorly, with two hairs; eye prominent, colorless, with bristle; occiput concave; antennal bands broad, faintly colored; mandibles reddish brown; a small black ocular fleck; whole head slightly testaceous, except oval fossae and part between occipital bands.

Prothorax short, sides rounded, without hairs, blackish brown lateral bands, extending around on posterior margin and almost meeting; coxal bands visible; interior of segment same color as head; metathorax larger, pentagonal, posterior margin broadly angulated on abdomen; three hairs at posterior angles; sides convex, widely diverging; blackbrown lateral bands curving inward; legs pale with golden tinge at end of tibiae.

Abdomen oval, colorless except faint median blotches on last three segments and sharply defined marginal band strongly piceous to brown, fainter on last two segments; each segment except the first two with two long hairs at outer angle; dorsum with long slender hairs.

Nirmus actophilus Kellogg and Chapman. Two males from Aphriza virgata, San Geronimo Island.

Nirmus complexivus Kellogg and Chapman. One specimen from *Limosa fedoa*, Playa Maria Bay.

Nirmus ductilis Kellogg and Chapman. One specimen from Amphispiza belli, San Martin Island.

Nirmus maritimus Kellogg and Chapman. Two specimens from Ptychoramphus aleuticus.

Nirmus ochropygus Nitzsch.

Male and female from Hacmatopus frazeri, San Martin Island.

Nirmus felix Giebel.

One specimen from Larus heermani, Todos Santos Island.

Philosophes backi Kellogg.

One female from Carrellanes amplies, Gundelonge Island.

The specimen is a little larger than the type, but agrees in all other respects. The type was taken from *Procellaria tethys*, on Wenman Island of the Galapagos group. Our specimen may be a straggler, though we have no records of *Procellaria* in this collection.

The abdomen of this specimen, and of the type female, is much more distinctly margined than is shown in the original drawing of the species. (The size might make this worthy of varietal name.)

Giebelia mirabilis Kellogg.

Four specimens from Puffinus opisthomelas, Natividad Island.

Lipeurus baculus Nitzsch.

One male from Columbigallina passerina socorroensis, Socorro Island.

Lipeurus confidens Kellogg.

Three specimens from Diomedea nigripes, Magdalena Bay; one from Diomedea immutabilis near San Geronimo Island.

Lipeurus concinnus Kellogg and Chapman.

Four specimens from Oceanodrama macrodactyla, Guadeloupe Island. One specimen from Diomedea immutabilis, near San Geronimo Island.

Lipeurus diversus Kellogg.

Four females from Oceanodrama macrodactyla, Guadeloupe Island.

Lipeurus gracilicornis var. major Kellogg.

Iwo females from Fregata aquila, San Benedicte Island.

Lipeurus faralloni Kellogg.

Two specimens, too young to identify positively, probably undescribed, from *Hacmatopus frazeri*, San Martin Island.

Lipeurus fuliginosus Tasch.

Three specimens from Puffinus opisthomelas, Natividad Island.

Lipemus testaceus Tasch.

Two specimens from Pullinus opisthomelas, Natividad Island.

Lipeurus limitatus Kellogg.

One female from Oceanodrama macrodactyla, Guadeloupe Island.

Eurymetopus taurus Nitzsch.

Two males from Diomedea nigripes, Magdalena Bay; one female and one immature specimen from the same albatross species, off Cape San Lucas. Another female bears the host record, Carpodacus amplus, Guadeloupe Island, but is evidently a straggler.

Colpecephalum funcbre Kellogg.

One specimen from Larus heermani, San Geronimo Island.

Colpocephalum unciferum Kellogg.

One female from Puffinus auricularis, Clarion Island.

Colpocephalum sp. juv.

A specimen, too young to be determined, from Puffinus auricularis, Clarion Island.

Colpocephalum milleri Kellogg and Kuwana.

Three specimens of this species from Anous ridgwayi, Socorro Island, and two from Sterna anaetheta, Socorro Island.

Colpocephalum flavescens Nitzsch.

Four specimens from Spectyto hypogaea, San Benito Island.

Colpocephalum dominicanum n. sp.

Two males from Oceanodrama macrodactyla, Guadeloupe Island. This specimen approaches spinosum of Piaget, from Francolinus capensis.

Description of male .- Body, length 1.72 mm.; width .60 mm.; strongly brown, concolorous with the exception of abdomen, which has slightly darker transverse blotches; head of unusual and distinctive shape.

Head, length .40 mm.; width .44 mm.; broadly rounded in front, with rather short hairs on the margin; ocular emargination not deep; eye small, convex; temples extended but slightly and moderately rounded, with three very long hairs; posterior angles angularly meeting occipital margin; occipital margin slightly concave; mandibles piceous.

Prothorax twice as bread as long; sides extended, coxac showing through very slightly darker; otherwise without distinct markings; sides with one long hair. Metathorax narrow in front; sides slightly arenate, diverging; coler brown, coxac showing through as darker blotches; dorsum with short scattered hairs; sides with one long hair; legs short, femora thick, lighter than general body color, and with numerous bristles.

Abdomen elongate; losal segment as broad as apex of thorax; broadest at segments 3 to 5; first segment with one hair at marginal angle; others with two long hairs; dorsum with many scattered long hairs; apical segment with fringe of shorter hairs; color almost uniformly dark brown, the marginal blotches showing slightly darker than the rest of the surface.

Colpocephalum tigrum n. sp.

Three males from Arenaria melanocephala, San Martin Island, and two from Aphrica virgata, San Geronimo Island. The described species nearest this is C. trimaculatum Piaget, but the broad, complete transverse blotches of the metathorax and first abdominal segment at once distinguish that species from tigrum.

Description of male.—Body, length, 1.60 mm.; width 64 mm.; color clear with brownish blotches, producing a strikingly and unusually marked Colpocephalum.

Head, length .35 mm.; width .42 mm.; front broadly rounded, semi-circular; four short and two medium hairs on the frontal margin, a long hair on lateral margin of front; ocular fringe prominent; eye distinct, with a prominent bristle; temples prominent, with three strong hairs; posterior margin of occiput concave; mandibles dark brown; ocular blotches dark brown, large, about twice as long as base of eye; a small brown blotch on signature; occipital bands light brown, except for darker spots at base and at apex converging; space between occipital bands brown; most of head with faint smoky brown color.

Prothorax about twice as broad as long; sides angulate at anterior third, with short hair at angle; coxae showing through as brown blotches; a shield-shaped brown ventral blotch, and a brown margin, the rest colorless. Metathorax at broadest part as broad as base of abdomen; sides angulate at middle, the angles bearing two bristles; colorless except for brown margin, a shield-shaped ventral blotch, and a short brown longitudinal line at base; coxae showing through as brown blotches; legs short, femora very thick; a faint brown spot on outer edge of femur near base, and a dark brown spot near tip of tibiae; tarsi faintly yellow; legs otherwise uncolored or faintly smoky.

Aldring, clongate oval, broadest at third and fourth segments; the segments of me ray equal length, a stout brithe at the province angle of each segment except the first with a long stout hair in addition to bristle, a single transverse row of weak hairs on dorsum of each segment except last two; first to sixth segments with a transverse narrow brown dorsal blotch, first to seventh with an irregular, darker marginal blotch, seventh segment with faint dorsal blotch, eighth with for rurall blotches; last segment with rows of minute hairs; genitaliand the; except for above blotches abdomen is colorless.

Menopon dissimile Kellogg.

One male from Pyrrholoxia venusta peninsulae, San Jose del Cabo.

Menopon infrequens Kellogg.

Three males from Larus heermani, San Geronimo Island.

Menopon paululum Kellogg and Chapman.

One immature male from Occanodrama macrodactyla, Guadeloupe Island.

Menopon singularis Kellogg.

Two males from Phacthon acthereus, Socorro Island.

Menopon becki Kellogg.

One male from Phacthon aethereus, Socorro Island.

Physostomum diffusum Kellogg.

One specimen from Ammodramus sanctorum, San Benito Island.

Physostomum subhastatum Durrant.

Three specimens from Pipilio albigula, San Jose del Cabo.

Physostomum fasciatus Piaget var. arcuatus nov. var.

Two specimens from Tyrannus vociferus, Cerros Island. The type of the species, taken from Larus capistratus, at the Zoological Garden in Amsterdam, was undoubtedly a straggler. Our specimens differ from the species figure and description in having two hairs directly anterior to the eye, the posterior angles of the head with two hairs, the sides of the prothorax with three long hairs, and the sides of the metathorax more arcuate for the posterior two thirds. The signature is piceous, and the front more convex.
