Rec. zool. Surv. India, 77: 31-37, 1980

THE CHEWING-LICE (PHTHIRAPTERA: INSECTA) FROM ANDAMAN AND NICOBAR ISLANDS WITH REMARKS ON SOME HOST RELATIONSHIPS

Bv

K. V. Lakshminarayana, (Miss) S. Vijayalakshmi and B. Talukdar Zoological Survey of India, Calcutta

During the survey tours of Drs. K. K. Tiwari, A. K. Mukherjee, and Mr. S. S. Saha of the Zoological Survey of India, they collected three samples of the chewing-lice comprising of three species from Megapodius freycinet Gaimard and Collocalia esculenta affinis Beavan. Of these, the former host has two subspecies in these Islands, and has considerable range of distribution in the Indo-Pacific, while the latter is endemic to the islands. Therefore, their parasites are of considerable interest from the point of distribution and study of host relationships, since the fauna of this region generally shows affinities with Burmese and Malayan fauna. Hither to, only three genera and species, viz., Goniodes minor confusio Clay, Oxylipeurus appendiculatus (Piaget) (Clay, 1938; 1940), and Columbicola cavifrons (Taschenberg) (Tendeiro, 1962) have been reported from these islands. The two first named species together with Dennyus (Collodennyus) medwayi Ledger (Ledger, 1970) are now reported from the above collection, and form the first new additions of chewing-lice from these islands to the National Zoological collections.

The material is mounted on slides, and the measurements are given in mm.

Dennyus (Collodennyus) medwayi Ledger, 1970

Dennyus (Collodennyus) medwayi Ledger, 1970. J. ent. Soc. S. Afr., 33 (2); 245, figs. 8-11. Type host; Collocalia gigas Hartert & Butler.

Material examined.—3 9 9, from Collocalia esculenta affinis Beavan, (ANB/72/186-190), Parka, c 14 km. off s. w. Malaka, Car Nicobar, 16. ii. 1972, coll. A. K. Mukherjee (Z. S. I. Reg. Nos. 706-708/H16).

Measurements: Width Length 0.44-0.46 0.37-0.40 Head 0.27-0.29 0.19-0.21 Prothorax 0.42 - 0.440.10 - 0.11Mesothorax 0.47-0.48 1.12-0.19 Metathorax 0.63-0.66 1.24-1.30 Abdomen 1.88-1.97 Total

Remarks.—Ledger (1970) described this species in detail from specimens off Collocalia gigas (Hartert & Butler), from Fraser's Hill, Pahang, Malaya, coll. Lord Medway, and named it after the collector. The present record on Collocalia esculenta affinis Beavan is quite interesting.

Dennyus (Collodennyus) distinctus Ferris is the normal species of lice that harbours on C. esculenta and its different subspecies cyanoptila, and desiderata (Ledger, 1970). Ledger (op. cit.) examined material from Malaya, North Borneo, Java, New Guinea, Rennell Is. and New Hebrides. The specimens under discussion are referred however, to D. (C.) medwayi Ledger, instead of the usual species D. (C.) distinctus Ferris because of the following diagnostic characters which make it distinct from the latter: the sternite II wider in the middle. the presence of fewer tergocentral setae on abdominal tergites I & II, and the subgenital plate without any additional and smaller central setae in the female. The setae in the lateral brushes of the abdomen vary not only from individual to individual, but also from segment to segment and on the two sides.

D. (C.) medwayi comes very close to D. (C.) distinctus. Ledger (op. cit.) while discussing the host relationship of Collocalia gigas, the type host of D. (C.) medwayi, quoted Medway & Well (1969) than the non-echolocating gigas shows morphological affinities with echo-locating 'grey swiftlets', though by behaviour it shows affinities with non-echolocating 'glossy swiftlets' to which group C. esculenta belongs. Medway & Wells (1969) contended that gigas may be a member of a monophyletic 'grey swiftlet' group which lost its capability of echolocation, or it evolved from an ancient non-echolocating 'glossy swiftlet' stock, which later acquired the features of the 'grey swiftlets' by convergence. Ledger (1970) supported the latter relationship, because D. (C.) medwayi found on C. gigas has its nearest relative in D. (C.) distinctus found on the 'glossy swiftlet', D. esculenta.

The present record helps us to go further to what Ledger suggested above. Here D. (C.) medwayi has been reported on a 'glossy swiftlet'

of the non-echolocating esculenta group viz., C. esculenta affinis Beavan, an endemic bird to these islands. The parasite species is also now being reported for the first time from Indian limits. C. esculenta as already stated is common in the Indo-Pacific, with its own parasite species, D. (C.) distinctus. We can only account for the present record in that possibly D. (C.) medwayi and D. (C.) distinctus are both sympatric species evolved on an ancestral stock of C. esculenta - C. gigas, and one of them might have been disappeared, and the other retained by different subspecies of C. esculenta and C. gigas; or the second species D. (C.) distinctus, has not so far been encountered on C. e. affinis and C. gigas possibly belong to the non-echolocating 'glossy swiftlet' stock, and gigas acquired the characters of 'grey swiftlet' group as has been contended by Medway & Wells and Ledger.

Remarks.—Piaget (1880) collections according to Clay (1940) contain at least three closely related species collected from different species and subspecies of Megapodius, though all of them were labelled as Goniocotes minor Piaget. Clay (1940) restricted the name Goniodes minor (Piaget) to those forms reported from Megapodius r. reinwardt Dumont. Another & from the same series was assigned the name G. ocrea (Piaget), and Hopkins & Clay (1952) suggested that the type host was "probably Eulipoa wallacei (G. R. Gray)". Clay (1940) described another subspecies G. minor confusio Clay from (M.n. nicobariensis) M. freycinet nicobariensis Blyth from Nicobar Island. K& cler (1939) included this species in his new genus Homocerus.

We refer our material to M. minor (Piaget), although the material has been collected from M. freycinet, and the measurements are slightly smaller (or some of them are identical) than with G. $minor\ s$. str., or G. m. confusio, by the shape of the head, laterally drawn prothorax which is nearer to the pterothoracic width, without continuous rows of setae on IV abdominal segment, and the long and broader basal plate in the male and the flattened posterior margin of the 'valve' and its chaetotaxy, the minute spines and striations on the genital region in the female. We have examined a paratype slide of G. $minor\ confusio$ Clay with $2\ 3\ 3$, $2\ 3\ 3$, from (M. nicobariensis) M. f. nicobariensis Blyth, Katchell, Nicobar Is., coll. $Dr\ R$. $Meinertzhagen\ (BMNH\ No.\ 3008)$ lent to the senior author by the British Museum (Nat. History), and though our specimens are smaller than these specimens, the male genitalia appear distinctly selerotized and stouter in proportion.

The present host *M. freycinet* Gaimard, otherwise harbours three more species of *Geniodes* besides *G. minor* viz., *G. major* (Piaget), *G. discogaster* (Taschenberg), (vide Clay, 1940), and *G. biordinatus* Clay (Emerson & Ward, 1958). *G. major* as the name indicates is a large form than *minor*, its prothorax not laterally produced, with numerous short setae on tergite IX, the very distinct male genitalia, and the shape of the female 'valve' and the chaetotaxy of the female genital region enables us to distinguish it from *minor*. *G. discogaster* can be recognized by the smaller size, expanded temples, large truncated coni, and the male genitalia which differ in *minor*. *G. biordinatus* can be recognized by the chaetotaxy of tergite IV, and female genital region. *G. ocrea* from *Eulipoa wallacei* (?) can be readily distinguished from all other species of *Goniodes* from the Megapodidae, by the distal prolongation of the post axial angle of the third antennal segment in the male at a glance.

The present record of G. minor (Piaget) collected from M. freycinet at two different places is interesting. In Nicobar Islands two subspecies are known, viz., M. f. nicobariensis Blyth and M. f. abbotti Oterholser from Great Nicobar. G. minor s. str., is so far known from the type host, M. reinwardt Dumont (New Guinea), M. r. yorki Mathews (N. Queensland), M. r. tumulus Gould (no data), M. f. cumingii Dillwyn (Labuan & S. E. Celebes), and M. f. pusillus Tweeddale (Philippine Islands), and G. m. confusio Clay from M. f.

nicobariensis Blyth (Nicobar). The subspecific determination was not available for the two hosts, but since one of them is from Great Nicobar, it is likely that it may be identical with *M. f. abbotti* Oberholser, and if it turns out to be the same species as we expect, then it is a new host for *G. minor* (Piaget). Emerson & Price (1972) while describing a new genus *Megapodiella* from *Megapodius* provided a list of all species known to that date on Megapodidae.

Genus Oxylipeurus Mjoeberg, 1910 sp. near Oxylipeurus appendiculatus (Piaget, 1880)

Oxylipeurus appendiculatus (Piaget) (Lipeurus), 1880. Pediculines: 356, pl. 28 fig 8. Type host: (Megapodium rubripes var gilberti) Megapodius freycinet gilbertii G. R. Gray.

Oxylipeurus major (Piaget) (Lipeurus), 1880. Pediculines : 357 nec p. 346. Type host : (Tinaņus canus. Error). M. f. nicobariensis Blyth.

Oxylipeurus oxycephalus (Taschenberg), (Lipeurus), 1882. Nova Acta Leop, 44: 178, pl 6 fig. 7. Type hosts: Oxylipeurus oxycephalus (Taschenberg); Mjocberg, 1910. Arc Zool, 6 (13): 92 Megapodius freycinet Gaimard & M. reinwadt Dumont.

Oxylipeurus appendiculatus (Piaget): Clay, 1938. Proc. zool. Soc. Lond. (B), 103: 160; Hopkins & Clay, 1952. Check List of Genera & Species of Mallophaga, Bull. Brit. Mus. [nat. Hist.]; 256, 258, 259.

Material examined.—2 3 3, 7 9 9, 9 ex (.), from Megapodius freycinet Gaimard, 24 km on N. S. Road, Nicobar, 9, iv. 1977, Coll. S. S. Saha. (Reg. Nos 741-749/H 16).

Genitalia				
Total	2.53-2.56		2.70-2.89	

Remarks.—Two species of Oxylipeurus are known from Megapodius reinwardt Dumont, and M. freycinet Gaimard viz., O. inaequalis (Piaget) (the type species of the genus) on the former, and O. appendiculatus (Piaget) on the latter host. Taschenberg (1882) reported O. appendiculatus both on M. reinwardt and M. freycinet as L. oxycephalus. Clay (1933) revised the genus and grouped both the species in a single group, and redescribed the species.

REFERENCES

Clay (1938) examined Piaget's type material of (M. nicobariensis gilbertii) M. f. gilbertii G. R. Gray and (M. n. nicobariensis) M. f. nicobariensis Blyth from Katchall, Nicobar. The present record can be considered at best as a new valuable addition to the National Zoological collections of the Z. S. I.

SUMMARY

This paper deals with a small interesting collection of chewing-lice from Andaman & Nicobar group of Islands. One of the species is now being reported for the first time since its description and from India on a new host which throws considerable light on the host relationship; the other two species are valuable new additions to the National zoological collections of the Zoological Survey of India.

ACKNOWLEDGEMENTS

The authors are grateful to the Director, Z. S. I., for facilities and encouragement. Their sincere thanks are also due to Drs. K. K. Tiwari, Jt. Director, A. K. Mukherjee, Superintending Zoologist, Mr. S. S. Saha, Assistant Zoologist of the Higher Chordate Division, Z. S. I., for collecting the material for our study. The senior author is highly indebted to the Department of Science & Technology, Govt. of India, for facilitating a visit to the British Museum (Natural History) London, and the authorities of the same museum for placing their valuable collections at the author's disposal for study and the material lent for further study in India, and to Dr (Miss) Theresa Clay, for several courtesies during this visit and otherwise. Miss Vijayalakshmi Swain expresses her gratitude to the Director, Z. S. I., for providing a research fellowship.
